## <sup>9</sup> Summary

<sup>10</sup> The transition to locally generated, decentralised, and renewable energy technologies is a promising pathway toward net-zero emissions and a decarbonised energy system. This transition requires systematic evaluation of potential future scenarios for technology adoption across multiple spatial scales. Computational energy system models are used for this purpose. <sup>11</sup> The *District Energy Model (DEM)* is a Python-based multi-energy system model designed to simulate scenarios from the neighbourhood to the regional scale, with a focus on the <sup>12</sup> integration of decentralised renewable energy technologies such as solar, wind, and biomass. <sup>13</sup> DEM can be used to execute simulation and optimisation studies at hourly resolution using <sup>14</sup> a snapshot-year methodology. It is released as an open-source Python library on [PyPi](#). The <sup>15</sup> model can be launched via a command-line interface, not requiring any Python programming <sup>16</sup> knowledge. Alternatively, it can be accessed programmatically through Python. DEM requires <sup>17</sup> two types of input: *configuration files* and *data files*. *Configuration files* specify the simulation <sup>18</sup> settings (e.g., included buildings, temporal scope, output variables) and define the energy <sup>19</sup> system configuration (e.g., scenarios, technologies, selected year). These configuration files <sup>20</sup> are provided in YAML format ([Ben-Kiki et al., 2009](#)). Configuration parameters may also be <sup>21</sup> passed directly to DEM in Python. *Data files* contain model data such as energy demand <sup>22</sup> profiles, generation potentials, and ambient conditions. They are provided in Apache Feather <sup>23</sup> format ([Apache Software Foundation, 2025](#)). For selected regions, these data files have been <sup>24</sup> pre-compiled from public datasets and made available in a public repository, providing a fully <sup>25</sup> parameterised model without requiring users to source or preprocess data. For example, data <sup>26</sup> for a full parameterisation of DEM is available for all municipalities in Switzerland. <sup>27</sup> <sup>28</sup> <sup>29</sup> <sup>30</sup> <sup>31</sup> DEM comes with a detailed [documentation](#), which includes step-by-step instructions, descriptions of modelling approaches and methods, and links to related publications and research.<sup>32</sup>

## <sup>33</sup> Statement of need

<sup>34</sup> Several countries have defined national net-zero emission targets ([IPCC, 2023](#)). Switzerland, for <sup>35</sup> example, aims to reach net-zero by 2050 ([The Federal Council, 2025](#)). Achieving such targets <sup>36</sup> generally requires a structural shift from large, centralised generation to decentralised renewable <sup>37</sup> resources, including solar, wind, and biomass ([Trutnevyyte et al., 2024; Van Liedekerke et al., 2025](#)). <sup>38</sup> To support energy system planning and policy design, scenario evaluation must be <sup>39</sup> carried out at local scales such as districts, municipalities, cities, or similarly sized regions. This <sup>40</sup> includes analysing system-integrated deployment of renewable energy generation, conversion,

41 and storage technologies, assessing alternative demand trajectories, and identifying solutions  
42 optimised for specific objectives such as cost, emissions, or security of supply.

43 DEM provides these functions with a specific focus on the use of local renewable energy  
44 resources and the integration of decentralised technologies within local system boundaries.  
45 Multiple energy system and demand scenarios can be defined, simulated, and compared.  
46 Increased penetration of variable, distributed resources raises the relevance of supply- and  
47 demand-side flexibility (Golmohamadi et al., 2024; Kachirayil et al., 2022). DEM models  
48 several flexibility options, including flexible electric vehicle charging, thermal and electrical  
49 storage, photovoltaic curtailment, and sector-coupling.

50 Existing multi-energy system models have been applied extensively in case studies of local  
51 energy scenarios, but they typically target a single location. Each new application requires  
52 reparameterisation and new data collection, including demand profiles, cost estimates, and  
53 technology characteristics. Data acquisition and preparation dominate the modelling workload  
54 in such studies. DEM removes this burden for selected regions by providing pre-compiled and  
55 pre-processed datasets assembled from public sources. Simulation and optimisation studies can  
56 therefore be executed with minimal configuration (e.g., selecting the buildings to include) while  
57 maintaining full flexibility to replace any pre-configured dataset with user-defined data when  
58 required. For regions not included in the provided dataset, users can construct the necessary  
59 data using the specifications provided in the documentation. DEM's input data architecture  
60 allows datasets to be provided at a large regional scale (e.g., an entire country) that can then  
61 be used to run simulations on any spatial subset of that data, such as individual municipalities  
62 or districts.

63 Optimisation is optional in DEM. Many scenario questions, such as assessing the impact  
64 of a specific technology, do not require optimisation because the system configuration is  
65 fixed, the technology capacities are predetermined, or the aim is to examine feasibility, energy  
66 balances, or system interactions rather than to identify an optimal design. Simulation is also  
67 appropriate when the objective is to reproduce prescribed operating behaviour, when data  
68 are insufficient to support a reliable optimisation formulation, or when the computational  
69 burden of optimisation is unjustified for large scenario ensembles. In these cases, DEM runs  
70 simulations without invoking the optimisation module, yielding short computation times and  
71 direct results. This distinguishes DEM from optimisation-centric energy system models that  
72 rely exclusively on optimisation and therefore cannot execute non-optimised scenario analyses  
73 with fixed configurations or purely exploratory simulations.

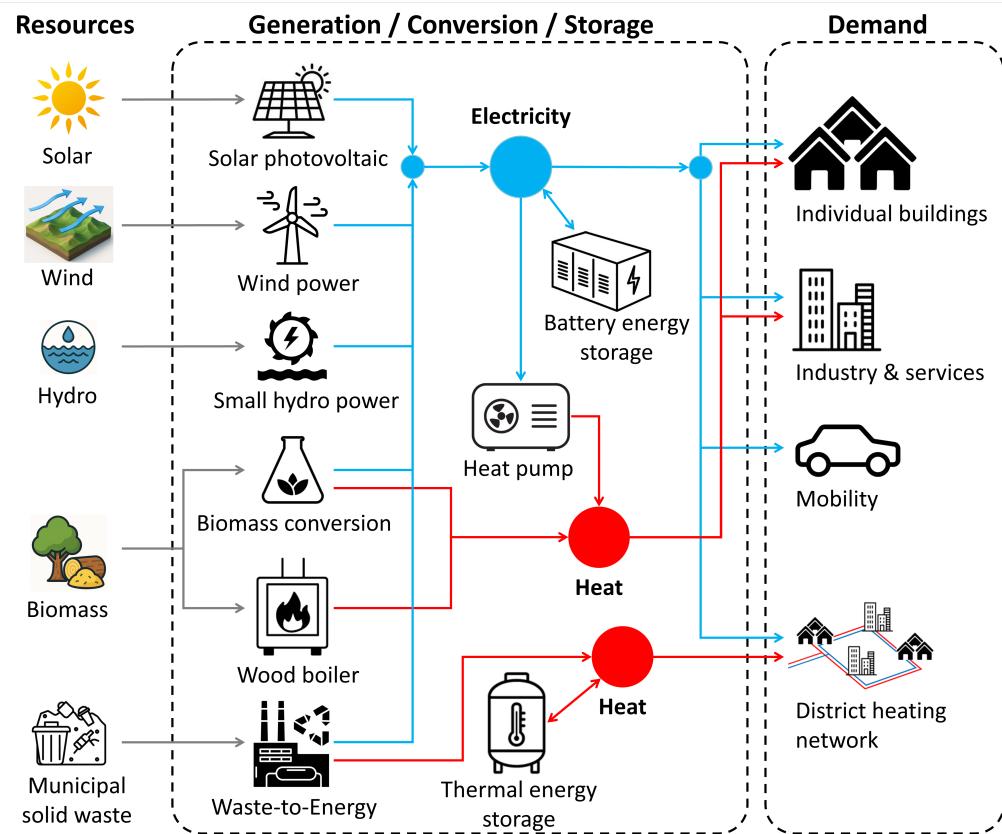

74 Initially developed within the framework of a research project, DEM is designed for a di-  
75 verse target audience extending from academia and research projects to decision-makers in  
76 municipalities, energy utilities, and the industrial sector.

## 77 Modelling approach

78 DEM simulates energy flows within a defined district using a hybrid bottom-up and top-down  
79 modelling approach. A “district” can represent any spatial scale, from a small group of buildings  
80 to an entire municipality or city. Building-level attributes are modelled individually (e.g., type,  
81 location, size, age, heat and electricity demand, heating system, and on-site solar potential).  
82 Other parameters are defined at district scale, including wind and biomass resources, ambient  
83 conditions, and mobility demand. Each simulation is constructed from three elements: a set of  
84 available resources (e.g., wind, solar, biomass, hydro), a set of technologies for generation,  
85 conversion, and storage, and a set of demand profiles for heat, electricity, and mobility. These  
86 elements interact through defined flows of resources and energy carriers such as electricity  
87 and heat. An example system layout is shown in Figure 1. DEM imposes no fixed limit on  
88 the number of buildings included, allowing customised definitions of district boundaries and  
89 building selections.

90 The workflow consists of: (1) input-data collection; (2) model parameterisation and config-  
 91 uration; (3) scenario generation; (4a) simulation; (4b) optimisation (optional); (5) output  
 92 generation.

93 The optimisation module in DEM is implemented using the Calliope framework ([Pfenninger &](#)  
 94 [Pickering, 2018](#)), which is based on the Pyomo optimisation programming environment ([Hart](#)  
 95 [et al., 2011](#)).

**Figure 1:** Schematic of an exemplary district energy system showing resources, generation, conversion, and storage technologies, and associated heat, electricity, and mobility demands. DEM supports many more technologies and scenarios than those illustrated here, as detailed in the [documentation](#).

## Acknowledgements

96 The development of DEM was carried out within the *Competence Centre Thermal Energy*  
 97 *Storage (CC TES)* at *Lucerne University of Applied Sciences and Arts (HSLU)*. The research  
 98 published in this publication was carried out with the support of the Swiss Federal Office of  
 99 Energy as part of the SWEET consortium EDGE. The authors bear sole responsibility for the  
 100 conclusions and the results presented in this publication.
